

S P E C I F I C A T I O N

PRESHAPED FORM

Inventor: Dan Rodlin

RELATED APPLICATIONS

This application is a continuation of patent application serial number 441,251, filed 5/15/95, issued as Patent No. 5,685,116 on 11/11/97, which is a continuation of patent application serial number 222,826 filed 4/05/94 now abandoned. The contents of the two prior applications are incorporated herein by reference.

BACKGROUND OF THE INVENTION**Field of the Invention**

The invention relates to prefabricated, light-weight, plaster relief forms to provide quick, low cost, installation of support members for constructing plaster coated decorative “plant-on’s” or “bump-outs” to the outside walls of dwelling structures.

Previous Art

Ornamentation and decoration of building structures such as residences and businesses is one important aspect of architecture. Marketing and sale of residences is enhanced by additional decorative detail. Pride of ownership is also enhanced by improved appearance of one’s building or residence. Ornamentation and decorative details are used extensively to add desirability and attractiveness to structures.

In certain regions of the country, such as the West and Southwest, the homes in the Mission style, and the Mediterranean style are quite popular. One of the popular methods of ornamentation used for these styles of homes is referred to in the building trades as “plant-ons” or “bump-outs”. The plant-ons may extend for a considerable length along the horizontal or vertical dimension of a wall or walls of a home or business. The plant-ons add a band or bands of relief to an otherwise blank façade that is presented by an unbroken expanse of plaster or stucco. The bands may extend completely around the outside perimeter of a building. For a conventional home of 2500 sq. ft., this may amount to 300 – 500 ft of bands for one single layer. The support for these bands are generally made of overlapping wooden boards including a first layer of 2 X 12 inches and a second layer of 2 X 8 inches. The boards are placed end to end in standard lengths of 8 to 12 ft to create a continuous relief band around the home. Similar bands may be constructed around door and window openings.

1 Attractive relief borders around windows and doors are also used to provide
2 enhancements to the architecture of homes and buildings. Such window and door borders have
3 been constructed using the above methods and materials.

4 These features are not necessary to the structural integrity of the building, but do add a
5 pleasing visual aesthetic appearance to a home or business.

6 One example of architectural relief products for attachment to homes are pre-shaped
7 foam members such as cornices, bases, sills and balusters, for example, supplied by High Tech
8 Foam Products, Inc of Corona, CA. Foam members may be provided in a wide variety of shapes
9 and sizes. The disadvantage of these members as supports for relief bands include the expense
10 of the items themselves, on the order of \$5 to \$6 per linear foot, and the additional labor and
11 material involved in adding a layer of screening or lath material over the foam to provide a
12 matrix for the plaster to adhere.

13 A conventional method of construction of plant-ons uses one or more planks of
14 overlapping boards attached to a wall at a particular height. To achieve a continuous band or
15 strip of relief, multiple lengths of uniform cross section boards are aligned end to end and
16 attached to the studs of a prepared wall. For conventional construction, the studs must be no
17 more than 24 inches on center, or less, according to the applicable local, state or national
18 building codes. The attachment is done with hammer driven nails, power gun driven nails, large
19 staple guns or the like. The boards are attached to the wall prior to the application of a plaster
20 coat or coats and prior to the application of a lath sheeting which will form a matrix or lattice for
21 supporting the plaster when it is applied. The lath is conventionally made of chicken wire or
22 expanded metal and attached with nails, staples or the like. The lath sheeting may be suspended
23 away from the wall and boards by a furring strip or strips interposed between the surface of the
24 wall and the sheeting. Self furred sheeting or wire may also be used to maintain the spacing
25 between the wall and the sheeting. An example of such wire is self furred metal lath made by
26 California Expanded Metal Products Company of Industry, CA. "Dimpled" or ribbed type self
27 furring metal lath provides a ¼ inch indentation in the metal lath to hold it away from the wall
28 allowing the plaster to fill the space between, insuring the lath is embedded. The spacing
29 between the lath and the wall or boards provides the opening for the plaster coat to surround the
30 lath and thereby bond firmly to the wall. A moisture barrier layer, of building paper, for

1 example, is applied between the boards and the lath sheeting by means of staples, nails, an
2 adhesive coating or the like.

3 The boards provide the relief pattern or bump-out desired. Additional screening is cut
4 and shaped by hand to conform to the protruding bump-out and nailed or stapled to the boards
5 and the wall.

6 Plaster is then applied to the bump-out and the wall to form the finished surface.

7 With reference to Fig. 10A, there is shown a schematic diagram of an exploded view of
8 one previous art method of assembly for a manually fabricated plaster relief form as described
9 above. A plurality of boards of desired width with the same cross section are aligned end to end
10 and nailed to the prepared wall to form a continuous plaster relief band to the desired length.
11 Additional lengths of wire screen or lath sections may be placed over the boards and formed by
12 hand to the contour of the boards. The additional sections are then typically nailed in place. Fig.
13 10B illustrates a cross section of such a relief form having a board attached to a stud framed
14 wall. A layer of moisture barrier paper and metal screen or lath are typically placed against the
15 wall and attached by nails to the studs. A plurality of spacers, such as furring strips or dimples in
16 the additional screen sections, are provided between the boards and the additional wire screen
17 sections to allow the subsequent plaster layer to flow into the openings of the wire screen
18 sections and fill the space between the screens and the top of the boards. Plaster is then typically
19 applied by hand using a hawk and trowel method or applied with a nozzle connected to a
20 machine as described above.

21 With reference to Fig. 10C, an additional improvement to the previous art method is
22 shown. Guide edge members are attached, typically by nailing into the form boards, to the edges
23 of the wire screen sections over the plaster form boards. The guide edges are spaced apart from
24 and aligned to be parallel with the plaster form boards. The guide edge members provide a guide
25 to the trowel or plaster dispensing nozzle as the plaster is applied, thereby allowing a uniform
26 depth of plaster to be applied easily. Representative guide edge members used in the trade are
27 made from 14 gauge wire such as the "CEMCORNER" corner reinforcement made by Cemco,
28 Covina Lane, CA. Or the "CornerAid" cover nose wire made by Stockton Products, Burbank,
29 CA.

30 The above-described method requires a number of hand operations, such a nailing the
31 boards, cutting the additional wire screen sections, hand forming the screen sections over the

1 boards and attaching the guide edge members, which significantly increases the cost of applying
2 plaster relief bands. It would be an advantage to provide a system to reduce the number of hand
3 operations required to apply plaster relief bands.

4 It is important to select boards made of wood which are of uniform cross section, in order
5 to achieve a visually pleasing effect. Boards which are not uniform in thickness or width will
6 show angular offsets at the ends where they meet. It is also important to select wood which is
7 well cured and has stable dimensional shape. If the wood twists or otherwise deforms after the
8 plaster has dried, unsightly cracks may appear. Cracks may also allow moisture to penetrate the
9 plaster and attack the wood beneath, or provide additional unwanted access to wood destroying
10 pests. Boards of suitable quality currently sell for \$2 to \$3 per linear foot. On a double band
11 board structure, the cost could be from \$15 to \$18 per linear foot, after including the costs of
12 boards, lath application and finished plaster.

13 The use of wood for forming the support structure for the plaster of decorative bands is
14 well known in the trade. As the costs of wood continue to increase, and the availability of high
15 quality boards continues to diminish, there is an urgent need to provide an alternative low cost
16 structure which will satisfy the desire for aesthetic enhancements to the various stucco and
17 plaster styles of home and office.

18 The non-uniformity of wooden boards in width and thickness can cause unsightly
19 mismatch in the appearance of the relief bands on a home. Either higher quality and thus higher
20 cost boards must be purchased, or labor intensive and expensive modification must be made on
21 the job site. This slows down the assembly process and further adds to the cost of building. It
22 would be an advantage to provide a support structure for plaster relief bands which would
23 guarantee uniformity in cross section aspect and thus match precisely when aligned at the ends.

24 The weight of the wood used for the band support structure creates several concerns.
25 Handling and aligning long lengths of boards takes considerable strength and capability. Moving
26 and holding a 12 foot length of board may require two workers to align successive boards. The
27 cost of shipping the wood used in making the band supports is also a factor in the cost of
28 building plaster or stucco homes. Wood often is shipped in a condition wherein it contains an
29 appreciable amount of water which significantly increases the weight of the wood. Wood
30 typically contains 30% or more water by weight. Such additional weight is of no use and in fact
31 may be harmful as described above. Wood used for decorative support may also be stored

1 outdoors while awaiting construction. It is possible for the wood to absorb moisture from the
2 surroundings thereby increasing its' weight even if it had been shipped in an originally dry state.
3 It would be an advantage to have a band support structure which is lighter in weight, thereby
4 reducing the cost and time of installation and the cost of shipping to the job site. It would be an
5 additional advantage to provide a band support structure which could not absorb water while
6 stored at a building site.

7 The use of wood as a building material combined with increased demands from a
8 growing population puts increasing pressure on our forest preserves. It would be an advantage to
9 provide a substitute material which would reduce the need to use wood except where it is most
10 effective, thereby preserving our valuable resources.

11 Even though the wood for plant on bands is covered by fire-resistant plaster, the building
12 codes still require the bands to be considered flammable structures. It would be an advantage to
13 provide a substitute material which was impervious to fire, and thereby add increased safety to
14 homes and buildings.

15 16 **SUMMARY OF THE INVENTION**

17 The general purpose of the invention is to provide light weight, low cost prefabricated
18 plaster relief form members which can be shipped to a construction job site in final form to
19 simplify the application of relief bands to the exterior of homes and buildings which are to be
20 coated with a cementitious coating, typically plaster or stucco.

21 According to one embodiment of the invention a prefabricated plaster relief form member
22 is provided for receiving and retaining a fluid cementitious coating, such as plaster, when the
23 member is attached to a prepared structural wall.

24 The member is configured from an openwork lattice sheet, preferably of an expanded
25 metal lath. The lattice sheet is adapted to receive and retain the plaster when the plaster when
26 the plaster is applied by hand or by spraying with a nozzle of a machine. The lattice sheet is
27 formed into a longitudinal channel having a top with opposed outer edges.

28 Two spaced apart sides extend away from the respective opposed outer edges, to
29 respective base edges. The respective base edges are aligned parallel to the top such that a
30 mounting plane is defined parallel to the top of the channel.

1 Two mounting flange portions, each extending outward and away from the base edges of
2 the respective sides, lie within the mounting plane parallel to the channel.

3 The member is thus defined as a channel having a length between two opposed ends and
4 a width between the two opposed sides. The channel is configured to have an essentially
5 uniform lateral cross section, perpendicular to the longitudinal dimension, protruding away from
6 the mounting plane.

7 The flange sections are adapted for mounting to the prepared structural wall such that a
8 plurality of such members mounted on the structural wall and adjoined end-to-end form a
9 continuous relief band protruding from the wall. The flange sections may be nailed or stapled to
10 the studs of a prepared wall after adjacent form members are aligned and adjoined end-to-end.

11 The regular cross section of similar prefabricated form members ensures an aesthetically
12 pleasing effect is easily achieved without shaving, trimming or selecting wooden boards.

13 The light weight and regular shape of these prefabricated members enable for easy and
14 low cost installation of the support forms needed for applying relief bands to stucco homes and
15 buildings.

16 The metal lath or lattice work is light, but has sufficient strength to support the plaster
17 coating and hold it in place while it cures. The prefabricated shape enables the construction of
18 plaster relief bands without the use of wood boards and the additional weight and shipping cost
19 involved. The cells and strands of the lattice work provides openings for the plaster to flow and
20 provides a secure network for the plaster to take hold while it hardens.

21 The uniform shape of the form member is dimensionally stable and not subject to
22 absorbing water. This eliminates the potential of warping that occurs with the use of wood as
23 support members for relief bands.

24 The combination of the structural support and the open lattice in the one element of the
25 prefabricated form member reduces the labor that otherwise is involved in attaching sheets of
26 screen wire to the wood planks used in conventional construction.

27 In another embodiment of the prefabricated form member, there is provided at least one
28 edge guide segment parallel to and spaced apart a preselected distance from at least one of the
29 channel outer edges. The edge guide segment is aligned parallel to the length of the member and
30 is configured to provide a guide edge for a tool. A connecting frame is provided for rigidly
31 connecting the edge guide segment to the member such that the edge guide segment provides a

1 secure guide edge for a tool used to apply the plaster or stucco coating to a preselected thickness
2 along the length of the member. A preferred thickness of plaster coating is about 7/8 inch
3 minimum in the finished state.

4 The prefabricated form member is typically formed from expanded, galvanized metal
5 having a preformed weight of about 3.4 pounds per square yard. The lattice is shaped into an
6 array of elongated hexagons, the hexagons having a major axis of about 1/2 inch and a minor axis
7 of about 3/8 inch. The adjacent hexagons along the minor axis being connected at opposed sides
8 by respective common side segments of about 1/8 inch in length, and adjacent hexagons along
9 the major axis being connected at the ends of respective 3/8 inch common end segments, while
10 the respective side and end segments are connected by corresponding right and left angled
11 linking segments.

12 A prefabricated form member as described above is non-permeable to water, non-
13 flammable and semi-rigid and has a lateral strength sufficient to support a plaster coating having
14 a thickness from about 1/2 inch in thickness, to about 2 inches in thickness.

15 It is an advantage in accordance with this invention to provide plaster relief form
16 members which eliminate the use of lumber in achieving architectural enhancement effects.

17 It is a further advantage in accordance with this invention to provide plaster relief form
18 members which reduce cost of installation.

19 It is a further advantage in accordance with this invention to provide plaster relief form
20 members which are lower in weight than equivalent lumber elements.

21 It is a further advantage in accordance with this invention to provide plaster relief form
22 members which reduce the cost of shipping members to the job site.

23 It is a further advantage in accordance with this invention to provide plaster relief form
24 members which are uniform in cross section and impervious to warping or cracking.

25 It is a further advantage in accordance with this invention to provide plaster relief form
26 members which reduce the number of hand operations and thereby reduce the cost of installation.

27 It is a further advantage in accordance with this invention to provide plaster relief form
28 members which are non-flammable.

29 It is a further advantage in accordance with this invention to provide plaster relief form
30 members which may be mass-produced in a wide variety of standard shapes at low cost.

1 It is a further advantage in accordance with this invention to provide plaster relief form
2 members which can be easily joined end-to-end to form visually uniform relief bands on outer
3 walls, around door or window openings and along the facia of a building. The relief bands have
4 stable shape with age and are resistant to warping and cracking due to moisture
5 absorption/desorption.

6 It is a further advantage of the present invention to use welded wire lath to form the form
7 member absent any other structural support member.

8 It is a further advantage to add edge guides to the welded wire form member.

9 It is a further advantage to form the member out of rib lath, preferably by placing the rib
10 members at the corners of the top and sides of the channel and in addition to depress the top from
11 the corners so that the ribs provide edge guides, and absent any other structural support member.

12 It is a further advantage to form the member out of woven wire lath also known as
13 chicken wire, and preferably of the self furring form, absent any other structural support
14 member, and in addition, preferably with edge guides applied to the corners of the top and side
15 of the channel.

16 It is a further advantage, where edge guides applied to corners of the top and sides of the
17 channel are cut-down to have shorter side extensions.

18 19 **BRIEF DESCRIPTION OF THE DRAWINGS**

20 For a further understanding of the objects and advantages of the present invention,
21 reference should be had to the following detailed description, taken in conjunction with the
22 accompanying drawings, in which like parts are given like reference numerals and wherein;

23 Fig. 1 is an exploded perspective view of prefabricated plaster relief forms members
24 aligned end to end in accordance with this invention.

25 Fig. 2 is a plan view of a section of expanded metal lath used as the open work lattice
26 material to make a preformed plaster relief form member in accordance with this invention.

31 guides in accordance with the invention.

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT OF THE INVENTION

With reference to Fig. 1, there is shown an embodiment of the prefabricated plaster relief form member in accordance with this invention, generally referred to by the numeral 20. The member 20 is shown aligned end-to-end with similar members 20a and 20b. The member 20 is formed from an open lattice material 22 such as 3.4 lb/sq. yd. diamond mesh expanded metal made by Western Metal Lath Company of San Leandro, CA. The lattice material 22 is bent on a tool such as a sheet metal brake in a metal shop to form a longitudinal channel having a protuberant contour 30 with a top surface 31, opposed sides 34, 36 at essentially right angles to surface 31, and opposed ends 38, 40. The sides 34, 36 of lattice material 22 are bent to form flanges 42, 44 extending at essentially right angles away from the respective sides 34, 36 of the member 20. The flanges 42, 44 are configured to lie in the same mounting plane 46 indicated by the arrows x, y. The mounting plane 46 and flanges 42, 44 are essentially parallel to the length L of the member 20. The depth D of the member 20 is typically about 1-1/2 inches, the width W typically about 6 to 12 inches and the length L typically 6 to 10 feet. The flanges 42, 44 extend a distance F typically about 1-1/2 inches respectively from each side 34, 35. The member 20 is configured so that each end 38, 40 can abut contiguously at each end 38, 40 with adjacent identical members, as indicated by members 20a and 20b, to form a continuous relief band when mounted on a prepared structural wall. The application and method of use of prefabricated plaster relief bands is described below.

The members 20, 20a, 20b would typically be fabricated at a remote site, such as a metal shop or manufacturing plant by using tools well known in the metal working trade.

A preferred manufacturing method for the prefabricated members 20 is an automated means such as high speed punches and presses operated with appropriately configured molds to achieve a desired contour. Finished members 20 would then be shipped to a job site for installation by lower cost tradespeople.

With reference to Fig. 2, there is shown a detail of a typical lattice material 22. A preferred lattice 22 is typically formed of galvanized steel expanded to provide an hexagonal close packed array 48 of cells 50 bounded by strands 52. The strands 52 are formed of galvanized sheet steel typically about 0.020 inches thick. The cells 50 are elongated hexagons with major axis 54 about 11/16 inch long and minor axis 56 about 5/16 inch wide. Alternatively, the lattice 22 may be formed of lighter or heavier expanded metal, such as 1.75 lb/sq. yd. Or 2.5

1 lb/sq. yd. For smaller or larger preformed members. A suitable material is the galvanized steel
2 diamond mesh of 3.4 lb/sq. yd. Made by Western Metal Lath Co. La Mirada, CA.\

3 With reference to Fig. 3, an alternative embodiment of a prefabricated plaster support
4 member in accordance with this invention is shown. A paper backed lattice material may be
5 used to make a member generally indicated by numeral 60. An example of such a paper backed
6 lattice material is "CEM-LATH K" made by Cemco, of Industry, CA. "CEM-LATH K" is a 3.4
7 lb/sq. yd. Diamond mesh metal lath 62 backed with asphalt saturated "Kraft" paper 64 which
8 may be used to form a plaster support member 60 in accordance with this invention. The paper
9 backing 64 may be used to limit the amount of plaster which is needed to cover the member 60
10 after the member 60 is applied to a prepared structural wall (not shown).

11 The paper 64 extends a suitable distance such as 1-1/2 to 2 inches beyond the flanges 42,
12 44 and 3nds 38, 40 of the metal lath 62. The paper 64 extension provides an overlap with
13 adjacent paper backed members (not shown), when aligned end to end, to ensure a continuous
14 moisture barrier which may be required by local or state building codes.

15 It is contemplated that the paper 64 may be applied to the back of the lath 62 before
16 forming the member 60. Application of the paper 64 to the back of the lath 62 may be made by
17 adhesive means such as a hot glue (not shown) between the paper 64 and the lath 62. The paper
18 64 and the lath 62 may then be positioned between an upper mold and a lower mold having a
19 desired shape (not shown). Application of sufficient pressure between the upper mold and lower
20 mold will cause the lath 62 and paper 64 combination to be shaped into the desired member 60.

21 Other preformed shapes for prefabricated plaster form members in accordance with this
22 invention are contemplated. With reference to Figs. 4 there is shown an embodiment of a
23 prefabricated angled member 80. The angled member 80 provides a means to fit a continuous
24 relief band around the corner of a building (not shown) without cutting and fitting straight
25 members. The member 80 is made from open work lattice material as described above. The
26 member 80 includes a first portion 82 and a second portion 84 joined at a common edge 86. The
27 portions 82 and 84 may be joined by suitable means such as spot-welding, hot gluing or wire
28 tying, as is well known in the trade. The portion 82 and portion 84 are indicated at right angles
29 to each other, but can be any desired angle to accommodate intersecting structural walls at other
30 than 90 degree angles. The portions 82, 84 are configured to have similar protuberant cross
31 sections and protrude in a direction normal to the respective intersecting walls. The portions 82,

1 84 have respective lengths L1 and L2 measured from the common edge 86 to respective ends 38,
2 40. The portions 82 and 84 have top surfaces 85a, 85b intersecting at edge 86. The portions 82
3 and 84 have respective sides 88a, 88b, and 90a, 90b between the respective walls and respective
4 top surfaces 85a, 85b. Mounting flanges 92a, 92b and 94a, 94b project outward from respective
5 sides 88a, 88b, and 90a, 90b. Flanges 92a, 92b and 94a, 94b are configured to lie in intersecting
6 mounting planes and are adapted to fit parallel to the respective adjacent intersecting structural
7 walls.

8 The member 80 is attached to the studs of a prepared structural wall by means of nails or
9 staples driven through the respective flanges 92a-94b. Self-tapping sheet metal screws are
10 typically used to attach the flanges 92a-94b to metal studs. Sharp pointed "Streaker" self-
11 tapping sheet metal screws available from Pacific Steel and Supply, San Leandro, CA, may be
12 used for light gauge metal studs.

13 The ends 38 and 40 of member 80 are configured as before to abut or overlap
14 contiguously with respective ends of prefabricated plaster form members having the same cross
15 section as the member 80. One such abutting relationship with a plaster form member 20 having
16 the same cross section as member 80 is indicated by the exploded view of member 20 shown in
17 Fig. 4.

18 It is often desired to fit the perimeter of door or window openings with decorative plaster
19 elements. With reference to Fig. 5, another embodiment of an angled prefabricated plaster form
20 member in accordance with this invention is shown and generally indicated by numeral 100. In
21 one embodiment, the member 100 is made from expanded metal lath as before described. A first
22 portion 102 is joined with a second portion 104 at a common edge 106. Portion 102 includes a
23 sheet of expanded metal lath bent to form spaced apart sides 110a and 110b, a top surface 114
24 and respective mounting flanges 116a and 116b. Portion 104 includes a sheet of expanded metal
25 lath bent to form spaced apart sides 118a and 118b, a top surface 115 and respective mounting
26 flanges 120a and 120b. Portions 102 and 104 are configured to be symmetrical about the
27 common edge 106. The mounting flanges 116a, 116b, 120a and 120b lie in the same mounting
28 plane indicated by arrows x, y. Flanges 116a, 116b and 120a, 120b are connected to the
29 respective top surfaces 114 and 118 by the depending sides 110a, 110b and 118a, 118b. The top
30 surfaces 114, 115 lie in the same plane and are parallel to the mounting flanges 116a, 116b,
31 120a, 120b.

1 ALTERNATIVE PREFORMED PLASTER RELIEF FORM MEMBER

2 The previous art method of attaching separate guide edge members to the hand formed
3 plaster relief forms incurs extra handling and additional cost due to high rate labor charges. With
4 reference to Fig. 6, there is illustrated a perspective view of a portion of an alternative preformed
5 plaster relief form in accordance with this invention, and generally referred to as numeral 150.
6 As before described with reference to Fig. 1, wherein similar reference numerals are used to
7 designate similar elements, the member 150 is formed of an open work lattice material 22. A
8 preferred lattice material is a diamond mesh expanded metal such as 3.4 lb/sq. yd galvanized
9 metal lath made by CEMCO of Covina Lane, Industry, CA. The lattice material 22 of member
10 150 is preformed to include a top surface 31 having opposed ends 38, 40. The top surface 31 has
11 a bending line along the surface 31. The bending line is normal to the opposed ends and defines
12 an edge 33. The lattice material 22 is bent along the edge 33 to define a side 34 extending
13 downward from the top surface 31. The side 34 extends downward a suitable distance from the
14 top surface 31, to a second bending line 35, for example, 1-1/2 inches. The lattice material 22 is
15 bent along the second bending line 35, to form a mounting flange 42 extending laterally outward
16 from the side 34 of the member 150 to a suitable distance F, e.g. 1-1/2 inches. A similar bending
17 line, edge, side and flange (not shown) may be formed in a symmetrical relationship to the side
18 34 as before described and shown in Fig. 1.

19 A prefabricated guide edge member 160 is shown in exploded relationship to the member
20 150 as member 160 for clarity. Guide edge member 160 is attached at a plurality of points 162
21 along a first edge 164 to the top surface 31 of the member 150. The edge member 160 is
22 attached at a second plurality of points 166 to the side 34 of member 150. The method of
23 attachment may be spot welding, or bonding with an adhesive such as hot glue. A preferred
24 guide edge member 160 is the standard Bullnose regular cover nose wire having standard 1-1/2
25 inch legs made by Stockton Products, Covina, CA. The guide member 160 includes a guide
26 edge 168 spaced apart from, and parallel to, the intersection of the top surface 31 and the side 34.
27 The guide edge 168 is spaced apart a suitable distance, e.g. 5/8 inch from the top surface 31 of
28 the member 150. The guide edge 168 provides an edge to guide a tool, such as a trowel, while
29 applying plaster to the member 150, in such a manner that a uniform plaster coating thickness is
30 easily achieved on the top surface 31. The guide member 160 includes a plurality of wire
31 support members 170 and 172 connecting the guide edge 168 and the respective top 31 and side

1 34 of the member 150. A similar guide edge 174 spaced apart from the side 34 by a suitable
2 distance, e.g. 5/8 inch provides an edge to guide a tool along the member 150 to achieve a
3 uniform plaster coating thickness along the side 34.

4 The exploded view of the member 160 illustrates corresponding attachment points 162
5 and 166, the connecting wires 170' and 172' and the guide edge 168'.

6 With reference to Fig. 7, there is shown in cross section along the viewing plane
7 indicated by 7-7 of Fig. 6, the contour of the edge guide member 160 attached to the top 31 and
8 the side 34 of the member 150 at attachment points 162, 166 respectively. The top guide edge
9 168 and side guide edge 174 are shown as wires attached to the connection wires 170 and 172
10 and spaced apart from the top surface 31 and the side 34 by a suitable distance, typically 5/8
11 inch.

12 13 ALTERNATIVE CROSS SECTIONS FOR PREFABRICATED PLASTER RELIEF FORMS

14 With reference to Fig. 8a and 8b there are shown alternative cross sections for prefabricated
15 plaster relief form members in accordance with this invention. Fig. 8a illustrates a member 200
16 having opposed sides 202, 203 configured in a stair-stepped shape to provide two layers of relief.

17 Fig. 8b illustrates a cross section of a prefabricated plaster relief form member 204
18 having a stair-stepped aspect with four corner edges 206, 208, 210, 212. Each edge 206-212 has
19 a respective guide edge members 214, 216, 218, 220. Each guide edge member 214-220
20 provides a top and a side guide edge 214a, b-220a,b spaced apart from the respective corner
21 edges 206-212 by a suitable distance, e.g. 5/8 inch laterally outward and vertically upward.

22 With reference to Fig. 9, the use of the prefabricated plaster relief form is herein
23 described. In use, a structural wall is prepared having a plurality of studs 180 spaced a suitable
24 distance apart and mounted vertically along a foundation 182. A layer of asphalted "Kraft"
25 paper 184 for a moisture barrier is applied to the studs 180. A first layer of wire mesh or screen
26 186 (commonly called chicken wire) is then attached to the wall over the paper 184. A line is
27 defined along the wall wherein the desired decorative architectural structure was to be placed. A
28 plurality of prefabricated plaster relief form members 200 is aligned end to end along the line
29 and attached to the wall by means of nails or staples 186 driven through respective mounting
30 flanges 42, 44 into the studs 180. The light weight but substantially rigid lattice material 22 and
31 uniformity of shape provided by the preformed members 200 would make the task of creating a

uniform, continuous relief band extremely easy. With reference again to the detail of Fig. 2, the array 48 of open cells 50 of the lattice material 22 provides ready access for the application of plaster to envelop the strands 52 and bond firmly with the lattice 22.

The prefabricated guide edges 160 and 190 of the preformed plaster relief form 200 provide guides for guiding a tool to apply plaster to a uniform thickness along the relief form members 200.

One method of applying a cementitious coating is the well known three step process. A first coat of cementitious material, typically plaster, called a scratch coat, would be applied, either by hand trowel or by spraying from a nozzle connected to a gun feeder, hopper/mixer and pumps as is well known to those skilled in the art.

One preferred formulation for the scratch coat is set forth in Table 1. It is within the teachings of this patent to use any other suitable cementitious material to form the coating for the wall and prefabricated plaster form 20.

| |
|--|
| 1 part Colton Portland Cement type II |
| 3 parts common coarse sand |
| 5 to 8 gallons of water per sack of cement, depending on the water content of the sand |

Table 1

The scratch coat covers the wall and the sides and top surface of the form members 20 to a uniform depth of about 3/8 inch. The scratch coat is cured for a suitable time, such as 24 to 48 hours, according to the State of California Uniform Building Code 1988 Edition page 4706, herein incorporated by reference.

A second coat of plaster about 1/4 to 3/4 inches, with a preferred thickness or 3/8 inch, called the brown coat, is applied similarly to the wall and plaster forms 20. The brown coat is cured for a suitable time such as 7 to 14 days minimum. A suitable formulation for the brown coat is the same as Table 1, with the addition of a 3 to 5 shovelsful of sand per sack of cement.

A final plaster coat incorporating the desired color is applied similarly to a depth of about 1/16 to 1/8 inch. The formulation for the color coat is typically a mechanically blended compound of portland cement, hydrated lime and inert aggregates (16/20 or 20/30 sand), such as

1 that supplied by La Habra Stucco, Anaheim, CA. Material standards preferably meet Federal
2 Specification SS-L-351, Type F for hydrated lime, and Type 1 ASTM C150-56: Federal
3 Specification SS-C-192B, for white portland cement.

4 5 FURTHER EMBODIMENTS

6 A further embodiment of the invention is illustrated in Fig. 11. This embodiment takes
7 advantage of an existing product used in construction. In this embodiment the relief form
8 member 200 is made of a metal mesh 202 of the type known as welded wire, preferably in the
9 form of 2"X2" mesh, using 16 or 17 gauge wire. Paper backing comes attached to the wire mesh
10 when it is made and sold as by manufacturers for plastering purposes. In this form it is referred
11 to in the industry as welded wire lath. An example is that used in a product sold as Stucco-Rite
12 by K-Lath of Fontana, CA. The attached Appendix A is a copy of K-Lath's catalogue
13 A465,09200/KLC, Bayline 5409 showing various forms of lath.

14 Referring to Fig. 11, the welded wire mesh 202 is formed as described above into a
15 channel shape having mounting flanges 204, sides 206 and a top 208. The mounting flanges 204
16 are preferably ½ inch to 1 ½ inch extending away from the sides 206. The height of the side 206
17 is dictated by the desired design dimension, 1½ inches being exemplary. Paper backing 210
18 follows the form of the channel and is attached to the wire mesh 202 by an interweaving as
19 known in its preparation as lath. The width of the top 208 is also a design choice, 6 to 12 inches
20 being exemplary. The relief form member can be of any selected length for the use, and can be
21 preformed in exemplary lengths such as 6 to 10 feet.

22 This embodiment has a further alternative in which a product known as double wire mesh
23 is used. The double wire mesh material is used in a lath product sold as Stucco Rite Double
24 Wire by K-Lath of Fontana, CA, as described in the catalogue identified above. The double
25 wires are provided at selected intervals. The double wire form provides a nailing space between
26 the double wires to catch the nail head and prevent movement during installation.

27 When forming the channel shape using the welded wire mesh, the bends can be
28 anywhere, but referring to Fig. 12, it is preferable to have lengthwise extending wires 212 at the
29 bends or corners, as well as having a lengthwise extending wire proximate the outer termination
30 214. Since the welded wire mesh comes in specified dimensions, whether single or double wire,
31 to place the lengthwise wires at the bends or corners dictates the dimensions of the channel. This

1 structure gives additional rigidity which aids in installation. The paper backing 210 is shown
2 attached to the wire mesh 202 by interweaving as is known in the manufacture of welded wire
3 lath. A second layer of paper 215 is commonly employed having an asphaltic or other
4 waterproofing component.

5 The foregoing alternatives using welded wire mesh can be used as described, or with
6 corner beads also known as edge metal or edge guides as previously described and shown
7 diagrammatically in cross-section in Fig. 13. Corner beads are sold by various manufacturers
8 such as CEMCO of Industry, CA. Appendix B is a copy of CEMCO's catalogue of Metal Lath
9 and Accessories. Without the corner beads, certain architecture styles such as Spanish or
10 mission finish are facilitated. With the corner beads or edge guides, a smooth finish is
11 achievable. The corner beads can be attached by any suitable means, such as by hot glue.
12 Referring to Fig. 13 the wire mesh 202 has corner beads 216 attached at the corners of the top
13 208 and sides 206. Paper backing 210 is shown.

14 Another alternative construction of the invention uses only corner bead members joined
15 together to form the channel. This is shown diagrammatically in Fig. 14 in which corner beads
16 220 and 222 form the flanges 224 and along with corner beads 226 and 228, form the sides 230
17 and the corner beads 226 and 228 form the top 232. To form the top 232, corner beads 226 and
18 228 may overlap as shown at P although they can abut. The four corner beads are joined along
19 their length by any desired means such as wire ties, welding or hot glue. Also, paper backing
20 234 is applied, held in place such as by hot glue, and can include an asphalt coated layer. The
21 corner beads can be any known type, such as bullnose, or straight wire edge guides.

22 Referring to Fig. 15, in another alternative the channel is constructed by using a product
23 known as rib lath. Rib lath is a known product, similar to the expanded metal described above,
24 but having parallel ribs of solid, unexpanded portions extending lengthwise between areas of
25 expanded metal. The rib lath is shown in the CEMCO catalogue. The ribs may be about 3/8"
26 wide and spaced apart about 1-1/8 inch with three expanded portions between them. Referring to
27 Fig. 15, the rib lath 238 has the ribs 240 and the expanded metal portions 242 between the ribs.
28 The rib lath 238 is formed into a channel shape as shown diagrammatically having raised corners
29 where the sides and top meet with ribs 240 at the corners to serve as edge guides. In Fig. 15, the
30 longer lines 240 represent the ribs and the shorter lines and spaces 242 represent the expanded
31 metal portions. The rib lath structure is preferably also used with paper backing as described

1 above. In this form the corner bead or edge guide is built into the channel form itself. The sides
2 of the channel could be convergent from top to flange to provide an edge guide for the sides, or
3 the sides could be bent, like the top so that the corner protrudes to provide an edge guide for the
4 sides.

5 Referring to Fig. 16, in another alternative series of structures any of the foregoing shapes
6 can be formed using woven wire also known as chicken wire for the basic channel shape. This
7 wire is referred to as Stucco Netting in the K-Lath Catalogue. It is preferably augmented with
8 paper backing and as desired with corner beads as described above. The self-furring form is
9 preferred to keep a space between the wire and the paper backing. The woven wire is formed
10 into a channel 250, with flanges 252, sides 254 and top 256. Corner beads 258 are attached as
11 well as paper backing 260.

12 Corner beads are commonly made with lengthwise wires at the apex to form a bullnose or
13 straight shape and undulating and straight wires combined to provide an extension away from the
14 apex. In the CEMCO catalogue this is shown on page 8 as CEMCORNER. Figs. 17a and 17b
15 shows this structure with wires 270, 272 and 274 defining an apex, and the remainder of the
16 structure of undulating wires 276 and straight wires 278 forming side extensions away from the
17 apex. In the present invention, referring to Figs. 17a and 17b, this type of corner bead can be
18 used as shown in the CEMCO catalogue, but in a further embodiment the side extensions can be
19 cut away to make it smaller. Selected places for lengthwise cutting away are shown at A-A, B-
20 B, C-C and D-D. The form created by the cutting away along line D is shown in Fig. 18.

21 In all of these alternative constructions, no underlying structural support member is used.
22 In particular any wood boards are absent.

23 In all of these further embodiments, the shape of the channel can be made in the stepped
24 form as shown in Figs. 8a and 8b except that the channel is made of materials as described in
25 these further embodiments and absent any additional underlying support such as wood boards.

26 While the foregoing detailed description has described the embodiments of the plaster
27 relief form member in accordance with this invention, it is to be understood that the above
28 description is illustrative only and not limiting of the disclosed invention. It will be appreciated
29 that it would be possible to modify the type of lattice material to include larger or smaller cells
30 and strands, to modify the shape of the cells and the material, to modify the cross section to
31 include non-uniform shapes, to add other structures to the plaster relief form member such as

1 flashing for interfacing with roofing members, to modify the coating of that lattice material by
2 paints and/or other rust preventative materials or to include or exclude various elements within
3 the scope and spirit of the invention. Thus the invention is to be limited only by the claims as set
4 forth below.

5
